

**book problems**

3.3 #20  $p$  is equal to one of  $3k$ ,  $3k + 1$  or  $3k + 2$ . When  $p = 3$  we can check directly what happens, so we need only consider the case  $p = 3k$  for  $k > 1$ . In this case  $p$  is not prime so we needn't check it after all. If  $p = 3k + 1$  then  $p^2 + 8 = 3k^2 + 6k + 9 + 8 = 3k^2 + 6k + 17$  and hence  $p^2 + 8$  is composite so we needn't consider this case either. If  $p = 3k + 2$  then  $p^2 + 8 = 9k^2 + 12k + 4 + 8 = 9k^2 + 12k + 12$  which is also composite. So, the only case we need to check is  $p = 3$  and we check to see that  $3^2 + 8 = 17$ , a prime, and  $3^3 + 4 = 31$  which is also prime.

4.2 #13 Since  $a \equiv b \pmod{n_1}$  and  $a \equiv b \pmod{n_2}$  there exist  $e_1$  and  $e_2$  such that  $a - b = e_1 n_1 = e_2 n_2$ . In particular,  $a - b$  is a common multiple of  $n_1$  and  $n_2$ . Since  $a - b$  is a common multiple of  $n_1$  and  $n_2$  we know that the least common multiple of  $n_1$  and  $n_2$  divides  $a - b$ . (This can be seen from the proof of Theorem 2.8) or can be explicitly seen: There exist  $x, y \in \mathbb{Z}$  so that  $n_1 x + n_2 y = \gcd(n_1, n_2)$ , therefore,

$$\frac{a - b}{\text{LCM}(n_1, n_2)} = \frac{(a - b) \gcd(n_1, n_2)}{n_1 n_2} = \frac{(a - b)x n_1}{n_1 n_2} + \frac{(a - b)y n_2}{n_1 n_2} \in \mathbb{Z}$$

**Non-book problems:**

1.  $n = 99991$  is prime.
2. The 100-th prime number is 541.
3. The primes less than 100000 whose last four digits are 9999 are: 49999, 59999, 79999.
4. The largest gap is 72, occurring at  $g(n) = p_{n+1} - p_n$  with  $n = 3385$ .
