Models of Motion

January 24, 2001

The Modeling Process

- It is based on experiment and/or observation.
- It is iterative.
 - ◊ For motion we have ≥ 6 iterations.
 - ◊ After each change in the model it must be checked by experimentation and observation.
- It is rare that a model captures all aspects of the phenomenon.

Linear Motion

- Motion in one dimension
 - ◊ Example – motion of a ball in the earth's gravity.
- $x(t)$ is the distance from a reference position.
 - ◊ $x(t)$ is the height of the ball above the surface of the earth.
- Velocity: $v = x'$
- Acceleration: $a = v' = x''$.

Return

- Acceleration due to gravity is (approximately) constant near the surface of the earth

$$F = -mg \quad g = 9.8m/s^2$$

- Newton's second law: $F = ma$
- Equation of motion: $ma = -mg$, which becomes

$$x'' = -g \quad \text{or} \quad \begin{array}{l} x' = v, \\ v' = -g. \end{array}$$

Return

Definitions

- Solving the system $\begin{array}{l} x' = v, \\ v' = -g \end{array}$
- Integrate the second equation:

$$v(t) = -gt + c_1$$

- Integrate the first equation:

$$x(t) = -\frac{1}{2}gt^2 + c_1t + c_2.$$

Resistance of the Medium

- Force of resistance $R(x, v) = -r(x, v)v$ where $r(x, v) \geq 0$.

- Different models

- ◊ Resistance proportional to velocity.

$$R(x, v) = -rv, \quad r \text{ a constant.}$$

- ◊ Magnitude of resistance proportional to the square of the velocity.

$$R(x, v) = -k|v|v.$$

Return

$$R(x, v) = -rv$$

- Total force: $F = -mg - rv$
- Newton's second law: $F = ma$
- Equation of motion:

$$mx'' = -mg - rv \quad \text{or} \quad \begin{array}{l} x' = v, \\ v' = -\frac{mg + rv}{m}. \end{array}$$

Return

$$R(x, v) = -rv \text{ (cont.)}$$

- The equation $v' = -\frac{mg + rv}{m}$ for v is separable.
- Solution is $v(t) = Ce^{-rt/m} - \frac{mg}{r}$.
- Notice

$$\lim_{t \rightarrow \infty} v(t) = -\frac{mg}{r}.$$

- The *terminal velocity* is $v_{\text{term}} = -\frac{mg}{r}$.

Return

$$R(x, v) = -k|v|v$$

- Total force: $F = -mg - k|v|v$.
- Equation of motion:

$$mx'' = -mg - k|v|v \quad \text{or} \quad \begin{array}{l} x' = v, \\ v' = -g - \frac{k|v|v}{m}. \end{array}$$

- The equation for v is separable.

Return

- Suppose a ball is dropped from a high point. Then $v < 0$.
- The equation is

$$\begin{aligned} v' &= \frac{-mg + kv^2}{m} \\ &= -\frac{k}{m} \left[\frac{mg}{k} - v^2 \right] \\ &= -\frac{k}{m} [\alpha^2 - v^2], \quad \text{where } \alpha = \sqrt{mg/k}. \end{aligned}$$

- The solution is

$$v(t) = \sqrt{\frac{mg}{k}} \frac{Ae^{-2t\sqrt{kg/m}} - 1}{Ae^{-2t\sqrt{kg/m}} + 1}.$$

- The terminal velocity is

$$v_{\text{term}} = -\sqrt{mg/k}.$$
